# Some exact constants for bilateral approximations in quasi-normed groups 

Oleh Lopushansky

#### Abstract

We establish inverse and direct theorems on best approximations in quasi-normed Abelian groups in the form of bilateral Bernstein-Jackson inequalities with exact constants. Using integral representations for quasi-norms of functions $\boldsymbol{f}$ in Lebesgue's spaces by decreasing rearrangements $\boldsymbol{f}^{*}$ with the help of approximation $\boldsymbol{E}$-functionals, error estimates are found. Examples of numerical calculations, spectral approximations of self-adjoint operators obtained by obtained estimates are given.

Keywords: Bernstein-Jackson inequalities, quasi-normed Abelian groups, exact approximation constants

MSC Classification: 42B35, 41A44, 41A17, 46B70

## 1 Introduction and main results

This article is devoted to the proof of a bilateral version of Bernstein-Jackson inequalities for quasi-normed Abelian groups. The case of similar inequalities on Gaussian Hilbert spaces of random variables was analyzed in the previous publication [10]. In the studied case, we use the approximation scale

$$
\mathcal{B}_{\tau}^{s}\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)=\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, q}^{1 / \vartheta}, \quad s+1=1 / \vartheta, \quad \tau=\vartheta q
$$

of compatible couple of quasi-normed Abelian groups with $0<\vartheta<1$ and $0<q \leq \infty$, defined by the Lions-Peetre method of real interpolation. It should be noted that in partial cases this scale coincides with the known scale of Besov spaces (see [1, Thm 7.2.4], [5, 6],[14, Thm 2.5.4]).

We also analyze the problem of accurate error estimates in quasi-normed spaces $L_{\mu}^{p}=L_{\mu}^{p}(\mathfrak{A})(0 \leq p \leq \infty)$ of $\mathfrak{A}$-valued functions $f: X \rightarrow \mathfrak{A}$ on a measure

[^0]space $(X, \mu)$. Using the decreasing rearrangement method (see e.g. [3, 4]), we reduce this problem to the simpler case for uniquely defined decreasing functions $f^{*}$ on $(0, \infty)$.

The scale of quasi-normed spaces $\mathcal{B}_{\tau}^{s}\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)$ endowed with the quasinorm $\|\cdot\|_{\mathcal{B}_{\tau}^{s}}$ is determined by the best approximation $E$-functional

$$
E\left(t, a ; \mathfrak{A}_{0}, \mathfrak{A}_{1}\right)=\inf \left\{\left|a-a_{0}\right|_{1}:\left|a_{0}\right|_{0}<t\right\}, \quad a \in \mathfrak{A}_{1}
$$

which fully characterizes the accuracy of error estimates (see e.g. [1, 11, 15]). In Theorem 1 we establish the bilateral version of Bernstein-Jackson inequalities for quasi-normed groups with the exact constants $c_{s, \tau}$ depend only on basis parameters $\mathcal{B}_{\tau}^{s}\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)$

$$
t^{s} E(t, a) \leq c_{s, \tau}|a|_{\mathcal{B}_{\tau}^{s}} \leq 2^{1 / 2}|a|_{0}^{s}|a|_{1}, \quad c_{s, \tau}=\left[\frac{s}{\tau(s+1)^{2}}\right]^{1 / \tau}
$$

for all $a \in \mathfrak{A}_{0} \bigcap \mathfrak{A}_{1}$ and $t, \tau>0$. The left inequality allows the unique extension to the whole approximation spaces $\mathcal{B}_{\tau}^{s}\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)$ in form of the Jackson-type inequality

$$
E(t, a) \leq c_{s, \tau} t^{-s}|a|_{\mathcal{B}_{\tau}^{s}} \quad \text { for all } \quad a \in \mathcal{B}_{\tau}^{s}\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)
$$

In Section 3 these results are applied to the quasi-normed Abelian groups $L_{\mu}^{p}=L_{\mu}^{p}(\mathfrak{A})$ with $0 \leq p \leq \infty$ and a positive Radon measure $\mu$ on a measure space $X$ of measurable functions $f: X \rightarrow \mathfrak{A}$ endowed with the $\kappa$-norm

$$
\|f\|_{p}= \begin{cases}\left(\int|f(x)|^{p} \mu(d x)\right)^{1 / p} & \text { if } 0<p<\infty \\ \operatorname{ess} \sup _{x \in X}|f(x)| & \text { if } p=\infty \\ \mu(\operatorname{supp} f) & \text { if } p=0\end{cases}
$$

where supp $f \subset X$ is a measurable subset such that $\left.f\right|_{X \backslash \operatorname{supp} f}=0$ and $f \neq 0$ almost everywhere on $\operatorname{supp} f$ with respect to the measure $\mu$. In Theorem 7 the equality

$$
f^{*}(t)=E\left(t, f ; L_{\mu}^{0}, L_{\mu}^{\infty}\right), \quad f \in L_{\mu}^{\infty}
$$

where $f^{*}$ is the decreasing rearrangement of $\mathfrak{A}$-valued functions $f \in L_{\mu}^{p}$ and, as a consequence, the following equalities

$$
\|f\|_{\tau / s}= \begin{cases}\left(\int_{0}^{\infty}\left[t^{s} f^{*}(t)\right]^{\tau} \frac{d t}{t}\right)^{1 / \tau} & \text { if } \tau<\infty \\ \sup _{0<t<\infty} t^{s} f^{*}(t) & \text { if } \tau=\infty\end{cases}
$$

are established. We also compute exact constants in the Jackson-type inequalities

$$
f^{*}(t) \leq t^{s} 2^{(s+1) / 2} c_{s, \tau}\|f\|_{\tau / s} \quad \text { for all } \quad f \in L^{\tau / s}
$$

that estimate measurable errors for decreasing rearrangements $f^{*}$, as well as the bilateral Bernstein-Jackson inequalities
$t^{-s} 2^{-(s+1) / 2} f^{*}(t) \leq c_{s, \tau}\|f\|_{\tau / s} \leq\|f\|_{0}^{s}\|f\|_{\infty} \quad$ for all $\quad f \in L^{0} \cap L^{\infty}, \quad$ where

$$
2^{-1 / 2 \theta} C_{\theta, q}=\left\{\begin{array}{cl}
c_{s, \tau} & \text { if } \tau<\infty \\
1 & \text { if } \tau=\infty
\end{array}\right.
$$

In particular, the following inequality holds,

$$
f^{*}(t) \leq \frac{2}{\pi t} \int|f| \mu(d x) \quad \text { for all } \quad f \in L_{\mu}^{1}
$$

The numerical algorithm resulting from the Theorem 7 was carried out on the example of inverse Gaussian distribution. Examples of applications for accurate estimates of spectral approximations of self-adjoint operators are given in Section 4.

Note that basic notations used in this work can be found in $[1,18]$.

## 2 Best approximation scales of quasi-normed Abelian groups

In what follows, we study the $\kappa$-normed Abelian groups $(\mathfrak{A},|\cdot|)$ relative to an operation " + ", where $\kappa$-norm $|\cdot|$ with the constant $\kappa \geq 1$ is determined by the assumptions (see e.g. [1, 11]):

```
\(|0|=0\) and \(|a|>0\) for all nonzero \(a \in \mathfrak{A}\),
\(|a|=|-a|\) for all \(a \in \mathfrak{A}\),
\(|a+b| \leq \kappa(|a|+|b|)\) with \(\kappa\) independent on \(a, b \in \mathfrak{A}\)
```

As is known, each $\kappa$-norm $|\cdot|$ can be replaced by an equivalent 1 -norm $|\cdot|^{\prime}$ such that $|\cdot|^{\prime} \leq|\cdot|^{\rho} \leq 2|\cdot|^{\prime}$ by taking $(2 \kappa)^{\rho}=2$ with a suitable $\rho>0$ (see e.g. [15]). We will not assume the completeness of groups.

Given a compatible couple $\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)$ of $\kappa_{\imath}$-normed groups $\left(\mathfrak{A}_{\imath},|\cdot|_{2}\right)$ with $\imath=\{0,1\}$ and $a=a_{0}+a_{1}$ in the sum $\mathfrak{A}_{0}+\mathfrak{A}_{1}$ such that $a_{\imath} \in \mathfrak{A}_{\imath}$ we define the best approximation $E$-functional $E\left(t, a ; \mathfrak{A}_{0}, \mathfrak{A}_{1}\right)$ with $a \in \mathfrak{A}_{0}+\mathfrak{A}_{1}$ and $t>0$ in the form (see [1, no.7])

$$
\begin{equation*}
E(t, a)=E\left(t, a ; \mathfrak{A}_{0}, \mathfrak{A}_{1}\right)=\inf \left\{\left|a-a_{0}\right|_{1}:\left|a_{0}\right|_{0}<t\right\}, \quad a \in \mathfrak{A}_{1} . \tag{1}
\end{equation*}
$$

Definition 1 For any $\tau=q \vartheta$ and $s+1=1 / \vartheta$ with $0<\vartheta<1$ and $0<q \leq \infty$ the $\kappa$-normed best approximation scales of Abelian groups are defined to be

$$
\begin{align*}
\mathcal{B}_{\tau}^{s}\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)= & \left\{a \in \mathfrak{A}_{0}+\mathfrak{A}_{1}:|a|_{\mathcal{B}_{\tau}^{s}}<\infty\right\} \\
|a|_{\mathcal{B}_{\tau}^{s}} & = \begin{cases}\left(\int_{0}^{\infty}\left[t^{s} E(t, a)\right]^{\tau} \frac{d t}{t}\right)^{1 / \tau} & \text { if } \tau<\infty \\
\sup _{0<t<\infty} t^{s} E(t, a) & \text { if } \tau=\infty\end{cases} \tag{2}
\end{align*}
$$

where (by [1, Lemma 7.1.6]) $\kappa=2 \kappa_{1} \max \left(\kappa_{0}^{s}, \kappa_{1}^{s}\right) \max \left(1,2^{-1 / q^{\prime}}\right) \max \left(1,2^{s-1}\right)$, $\left(1 / q^{\prime}=1-1 / q\right)$.

Given a compatible couple $\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)$, we also define the quadratic functional of Lions-Peetre's type (see e.g. [12, 15])

$$
K_{2}(t, a)=K_{2}\left(t, a ; \mathfrak{A}_{0}, \mathfrak{A}_{1}\right)=\inf _{a=a_{0}+a_{1}}\left(\left|a_{0}\right|_{0}^{2}+t^{2}\left|a_{1}\right|_{1}^{2}\right)^{1 / 2}, \quad t>0
$$

We will use the quadratically modified real interpolation method. Define the interpolation Abelian group of Lions-Peetre's type $\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, q}$ endowed with the quasinorm $\|\cdot\|_{\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, q}}$,

$$
\begin{aligned}
K_{\theta, q}\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)= & \left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, q}=\left\{a \in \mathfrak{A}_{0}+\mathfrak{A}_{1}\right\}, \\
|a|_{\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, q}} & = \begin{cases}\left(\int_{0}^{\infty}\left[t^{-\vartheta} K_{2}(t, a)\right]^{q} \frac{d t}{t}\right)^{1 / q} & \text { if } q<\infty \\
\sup _{0<t<\infty} t^{-\vartheta} K_{2}(t, a) & \text { if } q=\infty .\end{cases}
\end{aligned}
$$

Following [7, 10], we extend the use of approximation constants $c_{s, \tau}$ to the case of arbitrary quasi-normed Abelian groups $\mathcal{B}_{\tau}^{s}\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)$ described in the classic works [15, 16], where

$$
c_{s, \tau}:=\left\{\begin{array}{cc}
{\left[\frac{s}{\tau(s+1)^{2}}\right]^{1 / \tau}} & \text { if } \tau<\infty  \tag{3}\\
1 & \text { if } \tau=\infty
\end{array}\right.
$$

is determined by the normalization factor $N_{\vartheta, q}$ from [1, Thm 3.4.1] to be

$$
\begin{equation*}
c_{s, \tau}=N_{\vartheta, q}^{1 / q}\left(\vartheta q^{2}\right)^{-1 / q \vartheta}, \quad N_{\vartheta, q}:=[q \vartheta(1-\vartheta)]^{1 / q} . \tag{4}
\end{equation*}
$$

The following theorem establishes the bilateral form of approximation inequalities with exact constants for the case of quasi-normed Abelian groups.

Theorem 1 The bilateral Bernstein-Jackson inequalities with the exact constant $c_{s, \tau}$

$$
\begin{equation*}
t^{s} E(t, a) \leq c_{s, \tau}|a|_{\mathcal{B}_{\tau}^{s}} \leq 2^{1 / 2}|a|_{0}^{s}|a|_{1} \quad \text { for all } \quad a \in \mathfrak{A}_{0} \cap \mathfrak{A}_{1} \tag{5}
\end{equation*}
$$

hold. There is a unique extension of Jackson's inequality on the whole approximation scale

$$
\begin{equation*}
E(t, a) \leq t^{-s} c_{s, \tau}|a|_{\mathcal{B}_{\tau}^{s}} \quad \text { for all } \quad a \in \mathcal{B}_{\tau}^{s}\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right), \quad r>0 \tag{6}
\end{equation*}
$$

Proof Let $0<q<\infty$ and $\alpha=|a|_{\mathfrak{A}_{1}} /|a|_{\mathfrak{A}_{0}}$ with a nonzero $a \in \mathfrak{A}_{0} \cap \mathfrak{A}_{1}$. Since

$$
K_{2}(t, a)^{2}=\inf _{a=a_{0}+a_{1}}\left(\left|a_{0}\right|_{0}^{2}+t^{2}\left|a_{1}\right|_{1}^{2}\right) \leq|a|_{0}^{2} \min \left(1, \alpha^{2} t^{2}\right)=\min \left(|a|_{0}^{2}, t^{2}|a|_{1}^{2}\right)
$$

or otherwise $K_{2}(t, a) \leq|a|_{0} \min (1, \alpha t)=\min \left(|a|_{0}, t|a|_{1}\right)$, we get the inequality

$$
|a|_{\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, q}} \leq|a|_{1}^{q} \int_{0}^{\alpha} t^{-1+q(1-\vartheta)} d t+|a|_{0}^{q} \int_{\alpha}^{\infty} t^{-1-\vartheta q} d t .
$$

Calculating the integrals and using that $\alpha=|a|_{1} /|a|_{0}$, we obtain

$$
|a|_{\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, q}} \leq \frac{\alpha^{q(1-\vartheta)}}{q(1-\vartheta)}|a|_{1}^{q}+\frac{\alpha^{-\vartheta q}}{\vartheta q}|a|_{0}^{q}=\frac{1}{q \vartheta(1-\vartheta)}\left(|a|_{0}^{1-\vartheta}|a|_{1}^{\vartheta}\right)^{q} .
$$

Let it be now $q=\infty$. Then the inequality

$$
t^{-\vartheta} K_{2}(t, a) \leq \min \left(t^{-\vartheta}|a|_{0}, t^{1-\vartheta}|a|_{1}\right)
$$

holds. Taking in this case $t=|a|_{0} /|a|_{1}$, we obtain that $t^{-\vartheta} K_{2}(t, a) \leq|a|_{0}^{1-\vartheta}|a|_{1}^{\vartheta}$. Combining previous inequalities and taking into account (4), we have

$$
\|a\|_{\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, q}} \leq\left\{\begin{array}{ll}
N_{\vartheta, q}^{-1}|a|_{0}^{1-\vartheta}|a|_{1}^{\vartheta} & \text { if } q<\infty  \tag{7}\\
|a|_{0}^{1-\vartheta}|a|_{1}^{\vartheta} & \text { if } q=\infty
\end{array}, \quad a \in \mathfrak{A}_{0} \cap \mathfrak{A}_{1} .\right.
$$

For further considerations, we need the functional

$$
K_{\infty}(v, a):=\inf _{a=a_{0}+a_{1}} \max \left(\left|a_{0}\right|_{\mathfrak{A}_{0}}, v\left|a_{1}\right| \mathfrak{A}_{1}\right) .
$$

Now we will use the known properties of the considered functionals that

$$
\begin{aligned}
v^{-\theta} K_{\infty}(v, f) \rightarrow 0 & \text { as } \quad v \rightarrow 0 \text { or } v \rightarrow \infty \\
t^{-1+1 / \theta} E(t, f) \rightarrow 0 & \text { as } v \rightarrow 0 \text { or } v \rightarrow \infty
\end{aligned}
$$

(see [1, Thm 7.1.7]). As a result, we get
$\int_{0}^{\infty}\left(v^{-\vartheta} K_{\infty}(v, a)\right)^{q} \frac{d v}{v}=-\frac{1}{\vartheta q} \int_{0}^{\infty} K_{\infty}(v, a)^{q} d v^{-\vartheta q}=\frac{1}{\vartheta q} \int_{0}^{\infty} v^{-\vartheta q} d K_{\infty}(v, a)^{q}$.
On the other hand, integrating by parts with the change $v=t / E(t, a)$, we get for $s+1=1 / \vartheta$ that
$\int_{0}^{\infty}\left(v^{-\vartheta} K_{\infty}(v, a)\right)^{q} \frac{d v}{v}=\frac{1}{\vartheta q} \int_{0}^{\infty}(t / E(t, a))^{-\vartheta q} d t^{q}=\frac{1}{\vartheta q^{2}} \int_{0}^{\infty}\left(t^{s} E(t, a)\right)^{\vartheta q} \frac{d t}{t}$.
From the definition $K_{\infty}$ and $K_{2}$, it follows that

$$
\begin{equation*}
K_{\infty}(t, a) \leq K_{2}(t, a) \leq 2^{1 / 2} K_{\infty}(t, a) \tag{8}
\end{equation*}
$$

(see [15, Remark 3.1]). Now, taking into account that

$$
\frac{1}{\vartheta q^{2}}\|a\|_{\mathcal{B}_{\tau}^{s}}^{\vartheta q}=\frac{1}{\vartheta q^{2}} \int_{0}^{\infty}\left(t^{s} E(t, a)\right)^{\vartheta q} \frac{d t}{t}=\int_{0}^{\infty}\left(v^{-\vartheta} K_{\infty}(v, a)\right)^{q} \frac{d v}{v}
$$

according to the left inequality from (8), we obtain

$$
\begin{equation*}
\frac{1}{\vartheta q^{2}}|a|_{\mathcal{B}_{T}^{s}}^{\vartheta q} \leq \int_{0}^{\infty}\left(v^{-\vartheta} K_{2}(v, a)\right)^{q} \frac{d v}{v}=|a|_{\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, q}}^{q} \tag{9}
\end{equation*}
$$

By using the right inequality from (8), we have

$$
\begin{array}{r}
|a|_{\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, q}}^{q}=\int_{0}^{\infty}\left(v^{-\vartheta} K_{2}(v, a)\right)^{q} \frac{d v}{v} \leq 2^{q / 2} \int_{0}^{\infty}\left(v^{-\vartheta} K_{\infty}(v, a)\right)^{q} \frac{d v}{v} \\
=\frac{2^{q / 2}}{\vartheta q^{2}} \int_{0}^{\infty}\left(t^{s} E(t, a)\right)^{\vartheta q} \frac{d t}{t}=\frac{2^{q / 2}}{\vartheta q^{2}}|a|_{\mathcal{B}_{\tau}^{s}}^{\vartheta q} .
\end{array}
$$

As a result, by virtue of (9) we have the inequalities

$$
\begin{equation*}
\left.|a|\right|_{\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, q}} ^{q} \leq \frac{2^{q / 2}}{\vartheta q^{2}}|a|_{\mathcal{B}_{\tau}^{s}}^{\vartheta q} \leq\left. 2^{q / 2}|a|\right|_{\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, q}} ^{q} \quad \text { with } \quad \tau=\vartheta q . \tag{10}
\end{equation*}
$$

That gives the following isomorphism with equivalent quasinorms

$$
\begin{equation*}
\mathcal{B}_{\tau}^{s}\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)=\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, q}^{1 / \vartheta} \tag{11}
\end{equation*}
$$

By [1, Lemma 7.1.2 and Thm 7.1.1] for each $v>0$ there is $t>0$ such that

$$
\begin{equation*}
\left(t^{s} E(t, a)\right)^{\vartheta} \leq v^{-\vartheta} K_{\infty}(v, a) \leq\left(t^{s} E(t-0, a)\right)^{\vartheta} . \tag{12}
\end{equation*}
$$

Since $|a|_{\mathcal{B}_{\infty}^{s}}^{\vartheta} \leq|a|_{\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, q}}$ for $q=\infty$, the inequalities (12) for any $v>0$ yield

$$
\begin{aligned}
v^{-\vartheta} K_{2}(v, a) & \leq v^{-\vartheta} 2^{1 / 2} K_{\infty}(v, a) \leq 2^{1 / 2}\left(t^{s} E(t-0, a)\right)^{\vartheta} \\
& \leq 2^{1 / 2}\left(\sup _{t>0} t^{s} E(t, a)\right)^{\vartheta}=2^{1 / 2}|a|_{\mathcal{B}_{\infty}^{s}}^{\vartheta}
\end{aligned}
$$

As a result, $|a|_{\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, q}} \leq 2^{1 / 2}|a|_{\mathcal{B}_{\infty}^{s}}^{\vartheta}$ and the isomorphism (11) holds for $q=\infty$.
Prove the Bernstein inequality (28). Combining (7) and (9), we obtain

$$
|a|_{\mathcal{B}_{\tau}^{s}}^{\vartheta} \leq \begin{cases}{\left[\frac{q}{1-\vartheta}\right]^{1 / q}|a|_{0}^{1-\vartheta}|a|_{1}^{\vartheta}} & \text { if } q<\infty  \tag{13}\\ |a|_{0}^{1-\vartheta}|a|_{1}^{\vartheta} & \text { if } q=\infty\end{cases}
$$

Thus, the second inequality (28) we get by setting $s+1=1 / \vartheta$ and $\tau=\vartheta q$.
Prove the inequality (27). Integrating $\min (1, v / t) K_{2}(t, a) \leq K_{2}(v, a)$, we obtain

$$
\int_{0}^{\infty}\left(v^{-\vartheta} \min (1, v / t)\right)^{q} \frac{d v}{v} K_{2}(t, a)^{q} \leq \int_{0}^{\infty}\left(v^{-\vartheta} K_{2}(v, a)\right)^{q} \frac{d v}{v}=|a|_{\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, q}}^{q} .
$$

Since the left integral can be rewritten as the following sum

$$
\int_{0}^{\infty}\left(v^{-\vartheta} \min (1, v / t)\right)^{q} \frac{d v}{v}=\int_{0}^{t} v^{(1-\vartheta) q-1} t^{-q} d v+\int_{t}^{\infty} v^{-\vartheta q-1} d v=\frac{1}{t^{\vartheta} N_{\vartheta, q}^{1 / q}}
$$

we obtain the inequality

$$
\left(\int_{0}^{t} \frac{v^{(1-\vartheta) q-1}}{t^{q}} d v+\int_{t}^{\infty} v^{-\vartheta q-1} d v\right)^{1 / q} K_{2}(t, a)=\frac{K_{2}(t, a)}{t^{\vartheta} N_{\vartheta, q}} \leq|x|_{\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, q}}
$$

As a result, $K_{2}(t, a) \leq t^{\vartheta} N_{\vartheta, q}|a|_{\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, q}}$. Hence, taking into account (8) and (12), we get

$$
v^{1-\vartheta} E(v, a)^{\vartheta} \leq t^{-\vartheta} K_{\infty}(t, a) \leq N_{\vartheta, q}|a|_{\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, q}} .
$$

Applying (10), we obtain

$$
v^{1-\vartheta} E(v, a)^{\vartheta} \leq 2^{1 / 2} N_{\vartheta, q}|a|_{\mathcal{B}_{\tau}^{s}}^{\vartheta} .
$$

Taking into account that $\vartheta=1 /(s+1)=q / \tau$, we obtain the inequality (27) for all $0<q<\infty$.

In the case $q=\infty$, we have

$$
t^{s} E(t, a) \leq \sup _{t>0} t^{s} E(t, a)=|a|_{\mathcal{B}_{\infty}^{s}}
$$

for all $a \in \mathcal{B}_{\infty}^{s}$. Thus, the inequality (27) holds for both cases.
Finally note that Bernstein-Jackson inequalities are achieved at $\tau=\infty$, so they are sharp.

Corollary 2 If the quasi-normed Abelian groups $\mathfrak{A}_{0}, \mathfrak{A}_{1}$ are compatible then the following isomorphism with equivalent quasi-norms holds,

$$
\begin{equation*}
\mathcal{B}_{\tau}^{s}\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)=\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, q}^{1 / \vartheta}, \quad s+1=1 / \vartheta, \quad \tau=\vartheta q . \tag{14}
\end{equation*}
$$

If compatible groups $\mathfrak{A}_{0}$ and $\mathfrak{A}_{1}$ are complete, the approximation group $\mathcal{B}_{\tau}^{s}\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)$ is complete.

Proof The isomorphism (14) immediately follows from (11) and Theorem 1. Note that if both compatible groups $\mathfrak{A}_{0}$ and $\mathfrak{A}_{1}$ are complete, the interpolation group $\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, q}$ is complete [1, Thm 3.4.2 \& Lemma 3.10.2]. By Theorem $1 \mathcal{B}_{\tau}^{s}\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)$ is complete.

Corollary 3 Let $\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)$, $\left(\mathfrak{A}_{0}^{\prime}, \mathfrak{A}_{1}^{\prime}\right)$ be compatible. If $T: \mathfrak{A}_{2} \rightarrow \mathfrak{A}_{\imath}^{\prime}(\imath=0,1)$ are quasiAbelian mappings, i.e. $T\left(a_{0}+a_{1}\right)=b_{0}+b_{1}$ and $\left|T a_{\imath}\right|_{\mathfrak{A}_{2}} \leq \kappa_{\imath}\left|b_{\imath}\right|_{\mathfrak{A}_{2}^{\prime}}$ with constants $\kappa_{\imath}$ [1, p.81], then there exists a constant $C>0$ such that

$$
T: \mathcal{B}_{\tau}^{s}\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right) \rightarrow \mathcal{B}_{\tau}^{s}\left(\mathfrak{A}_{0}^{\prime}, \mathfrak{A}_{1}^{\prime}\right) \quad \text { and } \quad|T a|_{\mathcal{B}_{\tau}^{s}\left(\mathfrak{A}_{0}^{\prime}, \mathfrak{A}_{1}^{\prime}\right)} \leq C|a|_{\mathcal{B}_{\tau}^{s}\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)}
$$

Proof It follows from (10), (11) and the boundness of

$$
T:\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, q} \rightarrow\left(\mathfrak{A}_{0}^{\prime}, \mathfrak{A}_{1}^{\prime}\right)_{\vartheta, q},
$$

where $C \leq 4^{1 / \vartheta}\left(\vartheta q^{2}\right)^{-1 / \vartheta q} \kappa_{0}^{s} \kappa_{1}$ that gives the required inequality.

Corollary 4 Let $0 \leq \vartheta_{0}<\vartheta_{1} \leq 1,0<q \leq \infty$ and $\vartheta=(1-\eta) \vartheta_{0}+\eta \vartheta_{1}$ $(0<\eta<1)$. If the quasi-normed Abelian groups $\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)$, $\left(\mathfrak{A}_{0}^{\prime}, \mathfrak{A}_{1}^{\prime}\right)$ are compatible and the inclusions

$$
\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta_{\imath}, q} \subset \mathfrak{A}_{\imath}^{\prime} \subset\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta_{\imath}, \infty}, \quad(\imath=0,1)
$$

are valid, the following isomorphism with equivalent quasinorms holds,

$$
\begin{equation*}
\mathcal{B}_{\vartheta q}^{(1-\vartheta) / \vartheta}\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)=\mathcal{B}_{\eta q}^{(1-\vartheta) / \vartheta}\left(\mathfrak{A}_{0}^{\prime}, \mathfrak{A}_{1}^{\prime}\right) . \tag{15}
\end{equation*}
$$

Proof Using (11) and the known equality $\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, q}=\left(\mathfrak{A}_{0}^{\prime}, \mathfrak{A}_{1}^{\prime}\right)_{\eta, q}[15]$, [8, Theorem 3 ] in the case $r=1$, we get the reiteration identity (15) with accuracy to quasinorm equivalency.

Corollary 5 The following continuous embedding hold

$$
\mathcal{B}_{\vartheta q}^{(1-\vartheta) / \vartheta}\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right) \leftrightarrow \mathcal{B}_{\vartheta p}^{(1-\vartheta) / \vartheta}\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right) \quad \text { with } \quad q<p .
$$

Proof It follows from (11), since for arbitrary $q<p$ the following continuous embedding $\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, q} \rightarrow\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, p}$ is true by virtue of [8, Lemma p. 385].

Corollary 6 If $\vartheta_{0}<\vartheta_{1}$ then the embedding $\mathfrak{A}_{1} \subset \mathfrak{A}_{0}$ yields

$$
\mathcal{B}_{\vartheta_{1} q}^{\left(1-\vartheta_{1}\right) / \vartheta_{1}}\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right) \subset \mathcal{B}_{\vartheta_{0} q}^{\left(1-\vartheta_{0}\right) / \vartheta_{0}}\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right) .
$$

Proof It follows from Corollary 4 and [1, Theorem 3.4.1(d)].

## 3 Exact constants in bilateral error estimates

Let $(\mathfrak{A},|\cdot|)$ be a $\kappa$-normed Abelian group. Consider a quasi-normed space $L_{\mu}^{p}=L_{\mu}^{p}(\mathfrak{A})$ with a positive Radon measure $\mu$ on a measure space $(X, \mu)$ of measurable functions $f: X \rightarrow \mathfrak{A}$ endowed with the $\kappa$-norm

$$
\|f\|_{p}= \begin{cases}\left(\int|f(x)|^{p} \mu(d x)\right)^{1 / p} & \text { if } 0<p<\infty \\ \operatorname{ess}^{\left(\sup _{x \in X}|f(x)|\right.} & \text { if } p=\infty \\ \mu(\operatorname{supp} f) & \text { if } p=0\end{cases}
$$

where supp $f \subset X$ is a measurable subset such that $\left.f\right|_{X \backslash \operatorname{supp} f}=0$ and $f \neq 0$ almost everywhere on $\operatorname{supp} f$ with respect to the measure $\mu$.

For a $\mu$-measurable function $f: X \rightarrow \mathfrak{A}$, we define the distribution function

$$
m(\sigma, f)=\mu\{x \in X:|f(x)|>\sigma\} .
$$

Denote by $f^{*}$ the decreasing rearrangement of $f$, where

$$
f^{*}(t):=\inf \left\{\sigma>0: m\left(\sigma, f_{\sigma}\right) \leq t\right\}
$$

with $f_{\sigma}(x)=f(x)$ if $|f(x)|>\sigma$ and $f_{\sigma}(x)=0$ otherwise (for details see [1, no 1.3]). The decreasing rearrangement $f^{*}$ is nonnegative nonincreasing continuous on the right function of $\sigma$ on $(0, \infty)$ which is equimeasurable with $f$ in the sense that

$$
m(\sigma, f)=m\left(\sigma, f^{*}\right) \quad \text { for all } \quad \sigma \geq 0
$$

In other words, the decreasing rearrangement of a function $f$ is a generalized inverse of its distribution function in the sense that if $m(\sigma, f)$ is one-to-one then $f^{*}$ is simply the inverse of $m(\sigma, f)$.

Since $f$ is rearrangeable, $\left\{\sigma>0: m\left(\sigma, f_{\sigma}\right) \leq t\right\}$ is nonempty for $t>0$ thus $f^{*}$ is finite on its domain.

In the case where $\mu(X)<\infty$, we consider $f^{*}$ as a function on $(0, \mu(X))$, since $f^{*}(t)=0$ for all $t>\mu(X)$. The set $\left\{\sigma>0: m\left(\sigma, f_{\sigma}\right)=0\right\}$ can be empty. If $f$ is bounded then $f^{*} \rightarrow\|f\|_{\infty}$ as $t \rightarrow 0_{+}$, otherwise, $f^{*}$ is unbounded at the origin.

As is also know (see e.g. [13]) for $f \in L_{\mu}^{p}$ with $p \geq 1$ that

$$
\int|f|^{p} \mu(d x)=p \int_{0}^{\infty} \sigma^{p-1} m(\sigma, f) d \sigma, \quad\|f\|_{p}^{p}=\int_{0}^{\infty} f^{*}(t)^{p} d t
$$

The couple $\left(L_{\mu}^{0}, L_{\mu}^{\infty}\right)$ is compatible in the interpolation theory sense (see e.g. [1, Lemma 3.10.3] or [8, no 1]). Given elements $f=f_{0}+f_{\infty}$ in the algebraic sum $L_{\mu}^{0}+L_{\mu}^{\infty}$, we define the best approximation $E$-functional $E\left(t, f ; L_{\mu}^{0}, L_{\mu}^{\infty}\right)$ with $t>0$ as (see e.g. [1, no 7])

$$
E(t, f)=E\left(t, f ; L_{\mu}^{0}, L_{\mu}^{\infty}\right)=\inf \left\{\left\|f-f_{0}\right\|_{\infty}:\left\|f_{0}\right\|_{0}<t\right\}, \quad f \in L_{\mu}^{\infty}
$$

In what follows, we use the equivalent parameters $0<\vartheta<1,0<q \leq \infty$, where $s+1=1 / \vartheta$ and $\tau=\vartheta q$. Following [10], the appropriate system of exact constants $C_{\theta, q}$ is defined by the normalization factor

$$
N_{\theta, q}=\left(\int_{0}^{\infty}\left|t^{-\theta} \mathcal{N}(t)\right|^{q} \frac{d t}{t}\right)^{-1 / q} \quad \text { with } \quad \mathcal{N}(t)=\frac{t}{\sqrt{1+t^{2}}}
$$

in the known interpolation Lions-Peetre method to be

$$
C_{\theta, q}=\left\{\begin{array}{cl}
\frac{2^{1 / 2 \theta}}{\left(q^{2} \theta\right)^{1 / q \theta}} N_{\theta, q}^{1 / \theta} & \text { if } q<\infty  \tag{16}\\
\left(\frac{\sin \pi \theta}{\pi \theta}\right)^{1 / 2 \theta} & \text { if } q=2 \\
2^{1 / 2 \theta} & \text { if } q=\infty
\end{array}\right.
$$

Remark 1 For this equivalent parameter system the sharp constant $c_{s, \tau}$ takes an equivalent form

$$
2^{-1 / 2 \theta} C_{\theta, q}=\left\{\begin{array}{cc}
c_{s, \tau} & \text { if } \tau<\infty \\
1 & \text { if } \tau=\infty
\end{array}\right.
$$

where the following dependencies between indexes are performed,

$$
2^{-1 / 2 \theta} C_{\theta, q}=[(1-\theta) / q]^{1 / q \theta}=\left(\theta q^{2}\right)^{-1 / q \theta} N_{\theta, q}^{1 / \vartheta}
$$

Fig. 1 3D-graph of $c_{s, \tau}=(s / \tau)^{1 / \tau}(s+1)^{-2 / \tau}$ for $s, \tau>0$
A graphical image of the normalized constant sharp constant $c_{s, \tau}$ in variables $s, \tau$ shown on Fig. 1.

Theorem 7 (a) For any $0<\vartheta<1$ and $0<q \leq \infty$ the equality

$$
\begin{equation*}
f^{*}(t)=E\left(t, f ; L_{\mu}^{0}, L_{\mu}^{\infty}\right), \quad f \in L_{\mu}^{\infty} \tag{17}
\end{equation*}
$$

and, as a consequence, the following equalities hold,

$$
\|f\|_{q \theta^{2} /(1-\theta)}= \begin{cases}\left(\int_{0}^{\infty}\left[t^{-1+1 / \theta} f^{*}(t)\right]^{q \theta} \frac{d t}{t}\right)^{1 / q \theta} & \text { if } q<\infty  \tag{18}\\ \sup _{0<t<\infty} t^{-1+1 / \theta} f^{*}(t) & \text { if } q=\infty\end{cases}
$$

(b) The Jackson-type inequality

$$
\begin{equation*}
f^{*}(t) \leq t^{1-1 / \theta} C_{\theta, q}\|f\|_{q \theta^{2} /(1-\theta)} \quad \text { for all } \quad f \in L_{\mu}^{q \theta^{2} /(1-\theta)}, \tag{19}
\end{equation*}
$$

as well as, the following bilateral Bernstein-Jackson-type inequalities are valid,

$$
\begin{equation*}
t^{-1+1 / \theta} f^{*}(t) \leq C_{\theta, q}\|f\|_{q \vartheta^{2} /(1-\theta)} \leq 2^{1 / 2 \theta}\|f\|_{0}^{-1+1 / \theta}\|f\|_{\infty} \tag{20}
\end{equation*}
$$

for all $f \in L_{\mu}^{0} \cap L_{\mu}^{\infty}$.

Proof (a) By definition, the functional $E(t, f)$ is the infimum of $\left\|f-f_{0}\right\|_{\infty}$ such that $\mu\left(\operatorname{supp} f_{0}\right) \leq t$. The next reasoning extends [1, Lemma 7.2.1] on the case of $\mathfrak{A}$-valued functions.

Put $g_{0}(x)=f(x)$ on the subset $\operatorname{supp} f$ and let $g_{0}(x)=0$ outside $\operatorname{supp} f$. Then we obtain $\left\|f-g_{0}\right\|_{\infty} \leq\|f-g\|_{\infty}$.

In a similar way, let $g_{\sigma}(x)=f(x)$ if $|f(x)|>\sigma$ and $g_{\sigma}(x)=0$ otherwise. Then for the number $\tau=\sup \{|f(x)|: x \neq \operatorname{supp} f\}$ we get $\operatorname{supp} f_{\tau} \subset \operatorname{supp} f$. It follows $\mu\left(\operatorname{supp} g_{\tau}\right) \leq t$. Since $\left\|f-g_{\tau}\right\|_{\infty} \leq \tau$ and $\left\|f-g_{0}\right\|_{\infty}=\tau$, we obtain

$$
E\left(t, f ; L_{\mu}^{0}, L_{\mu}^{\infty}\right)=\inf _{\sigma}\left\{\left\|f-g_{\sigma}\right\|_{\infty}: \mu\left(\operatorname{supp} g_{\sigma}\right) \leq t\right\}
$$

where the rigth hand side is equal to $f^{*}$. As a result, the equality (17) holds.
Using the best approximation $E$-functional, we define the quasi-normed space

$$
\begin{equation*}
E_{\theta, q}\left(L_{\mu}^{0}, L_{\mu}^{\infty}\right)=\left\{f \in L_{\mu}^{0}+L_{\mu}^{\infty}:\|f\|_{E_{\theta, q}}<\infty\right\} \tag{21}
\end{equation*}
$$

$$
\|f\|_{E_{\theta, q}}= \begin{cases}\left(\int_{0}^{\infty}\left[t^{-1+1 / \theta} E(t, f)\right]^{q \theta} \frac{d t}{t}\right)^{1 / q \theta} & \text { if } q<\infty  \tag{22}\\ \sup _{0<t<\infty} t^{-1+1 / \theta} E(t, f) & \text { if } q=\infty\end{cases}
$$

By the known approximation theorem (see [1, Thm 7.2.2]) the isometric isomorphism

$$
\begin{equation*}
E_{\theta, q}\left(L_{\mu}^{0}, L_{\mu}^{\infty}\right)=L_{\mu}^{q \theta^{2} /(1-\theta)}, \quad\|f\|_{E_{\theta, q}}=\|f\|_{\vartheta^{2} q /(1-\theta)} \tag{23}
\end{equation*}
$$

holds for all $f \in L_{\mu}^{q \theta^{2} /(1-\theta)}$. Combining equalities (17), (21) and (23), we get the equality (18).
(b) In what follows, we use the classic integral of the real interpolation method

$$
\begin{equation*}
\|f\|_{\theta, q}=\left(\int_{0}^{\infty}\left|t^{-\theta} f(x)\right|^{q} \frac{d t}{t}\right)^{1 / q}, \quad 0<\theta<1,0<q<\infty . \tag{24}
\end{equation*}
$$

Let us consider the quadratic $K_{2}$-functional (see e.g. [12, App. B]) for the interpolation couple of quasi-normed groups $\left(L^{0}, L^{\infty}\right)$,

$$
\begin{aligned}
K_{2}(t, f) & =K_{2}\left(t, f ; L_{\mu}^{0}, L_{\mu}^{\infty}\right) \\
& =\inf _{f=f_{0}+f_{\infty}}\left\{\left(\left\|f_{0}\right\|_{0}^{2}+t^{2}\left\|f_{\infty}\right\|_{\infty}^{2}\right)^{1 / 2}: f_{0} \in L_{\mu}^{0}, f_{\infty} \in L_{\mu}^{\infty}\right\},
\end{aligned}
$$

determining the real interpolation quasi-normed Abelian group

$$
\left(L_{\mu}^{0}, L_{\mu}^{\infty}\right)_{\theta, q}:=K_{\theta, q}\left(L_{\mu}^{0}, L_{\mu}^{\infty}\right)=\left\{f=f_{0}+f_{\infty}:\left\|K_{2}(\cdot, f)\right\|_{\theta, q}<\infty\right\}
$$

which is endowed with the norm

$$
\|f\|_{K_{\theta, q}}= \begin{cases}N_{\theta, q}\left\|K_{2}(\cdot, f)\right\|_{\theta, q} & \text { if } q<\infty \\ \sup _{t \in(0, \infty)} t^{-\theta} K_{2}(t, f) & \text { if } q=\infty .\end{cases}
$$

Note that for any $0<\vartheta<1$ and $q=2$ the following equalities hold,

$$
N_{\theta, 2}=\|\mathcal{N}\|_{\theta, 2}^{-1}=\left\|K_{2}(\cdot, 1)\right\|_{\theta, 2}^{-1}=\left(\frac{2 \sin \pi \theta}{\pi}\right)^{1 / 2} .
$$

In fact, the relationship between the weight function $\mathcal{N}(t)^{2}=t^{2} /\left(1+t^{2}\right)$ and the quadratic $K_{2}$-functional is explained by the formula

$$
N_{\theta, 2}=\|\mathcal{N}\|_{\theta, 2}^{-1}=\left\|K_{2}(\cdot, 1)\right\|_{\theta, 2}^{-1}
$$

(see e.g. [12, Ex. B.4]). It follows from

$$
\min _{z=z_{0}+z_{1}}\left(\alpha_{0}\left|z_{0}\right|^{2}+\alpha_{1}\left|z_{1}\right|^{2}\right)=\alpha_{0} \alpha_{1}|z|^{2} \alpha_{0}+\alpha_{1}
$$

for a fixed $\alpha_{0}, \alpha_{1}>0$ and a complex $z$. This minimum is achieved when

$$
\alpha_{0} z_{0}=\alpha_{1} z_{1}=\frac{\alpha_{0} \alpha_{1} z}{\left(\alpha_{0}+\alpha_{1}\right)}
$$

Thus, $K_{2}(t, 1)$ is minimized when $f_{0}, f_{1}$ are such that

$$
f_{0}=t^{2} f_{1}=\frac{t^{2}}{1+t^{2}}
$$

By integrating the above functions (see e.g. [12, Ex. B.5, Thm B.7]) it follows that the normalization factor $N_{\theta, 2}$ is equal to $N_{\theta, 2}=(2 \sin \pi \theta / \pi)^{1 / 2}$.

In particular, the equalities (17),

$$
\begin{aligned}
f^{*}(t) & =\inf \left\{\sigma: m\left(\sigma, f_{\sigma}\right) \leq t\right\} \\
& =\inf \left\{\left\|f-f_{0}\right\|_{\infty}:\left\|f_{0}\right\|_{0}<t\right\}=E\left(t, f ; L_{\mu}^{0}, L_{\mu}^{\infty}\right), \quad f \in L_{\mu}^{\infty},
\end{aligned}
$$

as well as, the isometric isomorphism (23),

$$
E_{\theta, q}\left(L_{\mu}^{0}, L_{\mu}^{\infty}\right)=L_{\mu}^{q \theta^{2} /(1-\theta)}, \quad\|f\|_{E_{\theta, q}}=\|f\|_{\vartheta^{2} q /(1-\theta)}
$$

allows calculating the exact form of best constants (16).

Corollary 8 The decreasing rearrangement for $q=2$ has the estimation

$$
\begin{equation*}
f^{*}(t) \leq t^{1-1 / \theta}\left(\frac{\sin \pi \theta}{\pi \theta}\right)^{1 / 2 \theta}\|f\|_{2 \theta^{2} /(1-\theta)} \quad \text { for all } \quad f \in L_{\mu}^{2 \theta^{2} /(1-\theta)} \tag{25}
\end{equation*}
$$

which for $\theta=1 / 2$ can be written as follows

$$
\begin{equation*}
f^{*}(t) \leq \frac{2}{\pi t} \int|f| \mu(d x) \quad \text { for all } \quad f \in L_{\mu}^{1} . \tag{26}
\end{equation*}
$$

Note that if $\theta \rightarrow 1$ then $\sin \pi \theta \rightarrow 0$ thus above inequalities disappear. One has a sense only for the quasi-normed group $L_{\mu}^{2 \theta^{2} /(1-\theta)}$ with $0<\theta<1$.

Corollary 9 The equality (18) with $s+1=1 / \vartheta$ and $\tau=\vartheta q$ takes the form

$$
\|f\|_{\tau / s}= \begin{cases}\left(\int_{0}^{\infty}\left[t^{s} f^{*}(t)\right]^{\tau} \frac{d t}{t}\right)^{1 / \tau} & \text { if } \tau<\infty \\ \sup _{0<t<\infty} t^{s} f^{*}(t) & \text { if } \tau=\infty\end{cases}
$$

for any $f \in L_{\mu}^{\tau / s}$. Then the Jackson-type inequality takes the form

$$
\begin{equation*}
f^{*}(t) \leq t^{-s} 2^{(s+1) / 2} c_{s, \tau}\|f\|_{\tau / s} \quad \text { for all } \quad f \in L_{\mu}^{\tau / s} \tag{27}
\end{equation*}
$$

and bilateral Bernstein-Jackson-type inequalities take the form

$$
\begin{equation*}
t^{s} 2^{-(s+1) / 2} f^{*}(t) \leq c_{s, \tau}\|f\|_{\tau / s} \leq\|f\|_{0}^{s}\|f\|_{\infty} \quad \text { for all } \quad f \in L_{\mu}^{0} \cap L_{\mu}^{\infty} . \tag{28}
\end{equation*}
$$

It instantly follows from the relations

$$
C_{\theta, q}=\left\{\begin{array}{cc}
2^{(s+1) / 2} c_{s, \tau} & \text { if } \tau<\infty \\
2^{(s+1) / 2} & \text { if } \tau=\infty
\end{array}, \quad \text { where } \quad \vartheta=\frac{1}{s+1}, \quad 2^{1 / 2 \theta}=2^{(s+1) / 2} .\right.
$$

Remark 2 The inequalities (28) is an extension on the case measurable functions the known best approximation Bernstein-Jackson inequalities. Whereas the inequality (27) is an extension of the approximation Jackson inequality. The scale of approximation quasi-normed Abelian groups is often denoted as

$$
\mathcal{B}_{\tau}^{s}\left(L_{\mu}^{0}, L_{\mu}^{\infty}\right):=E_{\theta, q}\left(L_{\mu}^{0}, L_{\mu}^{\infty}\right),
$$

where the space $\mathcal{B}_{\tau}^{s}$ coincides with a suitable extension of the Besov type quasinormed groups (see e.g. [1, Thm 7.2.4], [18, Def. 4.2.1/1]). The scale of quasi-normed Besov Abelian groups for another approximation couples is described in [7].

## 4 Examples of bilateral estimates with exact constants

Taking into account the previous statements, we can give typical examples of Bernstein-Jackson inequalities with explicit constants for different types of best approximations.

Example 1 (Applications to classic Besov scales) Let $\mathfrak{A}_{0}=L^{p}\left(\mathbb{R}^{n}\right)$ with $(1<p<\infty)$. As is known (see e.g. [14]) each real-valued function $a \in L^{p}\left(\mathbb{R}^{n}\right)$ can be approximated by entire analytic functions $g \in \mathcal{E}_{p}^{t}\left(\mathbb{C}^{n}\right)$, where $\mathcal{E}_{p}^{t}\left(\mathbb{C}^{n}\right)$ means the space of entire analytic functions on $\mathbb{C}^{n}$ of an exponential type $t>0$ with restrictions to $\mathbb{R}^{n}$ belonging to $L^{p}\left(\mathbb{R}^{n}\right)$. The best approximations can be characterized by the best approximation functional

$$
E\left(t, a ; \mathcal{E}_{p}, L^{p}\left(\mathbb{R}^{n}\right)\right)=\inf _{t>0}\left\{\|a-g\|_{L^{p}\left(\mathbb{R}^{n}\right)}: g \in \mathcal{E}_{p}^{t}\left(\mathbb{C}^{n}\right)\right\}
$$

where the subspace $\mathfrak{A}_{1}=\mathcal{E}_{p}$ with $\mathcal{E}_{p}=\bigcup_{t>0} \mathcal{E}_{p}^{t}\left(\mathbb{C}^{n}\right)$ is endowed with the quasinorm

$$
|g|_{\mathcal{E}_{p}}=\|g\|_{L^{p}\left(\mathbb{R}^{n}\right)}+\{\sup |\zeta|: \zeta \in \operatorname{supp} \hat{g}\}, \quad g \in \mathcal{E}_{p}
$$

defined using the support supp $\hat{g}$ of the Fourier-image $\hat{g}$. Then according to Theorem 1 the corresponding approximation inequalities take the form

$$
\begin{aligned}
t^{s} E\left(t, a ; \mathcal{E}_{p}, L^{p}\left(\mathbb{R}^{n}\right)\right) & \leq c_{s, \tau}\|f\|_{B_{p, \tau}^{s}\left(\mathbb{R}^{n}\right)} \leq 2^{1 / 2}|a|_{\mathcal{E}_{p}}^{s}\|a\|_{L^{p}}, a \in \mathcal{E}_{p} \cap L^{p}\left(\mathbb{R}^{n}\right), \\
E\left(t, a ; \mathcal{E}_{p}, L^{p}\left(\mathbb{R}^{n}\right)\right) & \leq t^{-s} c_{s, \tau}\|a\|_{B_{p, \tau}^{s}\left(\mathbb{R}^{n}\right)}, \quad a \in B_{p, \tau}^{s}\left(\mathbb{R}^{n}\right),
\end{aligned}
$$

In this case the approximation scale

$$
\mathcal{B}_{\tau}^{s}\left(\mathcal{E}_{p}, L^{p}\left(\mathbb{R}^{n}\right)\right)=\left(\mathcal{E}_{p}, L^{p}\left(\mathbb{R}^{n}\right)\right)_{\vartheta, q}^{1 / \vartheta}
$$

exactly coincides with the classic Besov scale denoted by $B_{p, \tau}^{s}\left(\mathbb{R}^{n}\right)$ (see [18, p.197]).

Example 2 (Applications to scales of periodic functions) Following e.g. [1, no 1.5], [17] we can write Bernstein-Jackson inequalities in a more general form. Let $X=\mathbb{T}$ be the 1 -dimensional torus and the Hilbert space $\mathfrak{A}_{1}=L^{2}(\mathbb{T})$ has the orthonormal basis $\left\{\mathfrak{e}_{k}=e^{2 \pi \mathrm{i} k t}: k \in \mathbb{Z}, t \in \mathbb{T}\right\}$. Let $\mathfrak{A}_{0}=\left\{\right.$ trigonometric polynomials $\left.a_{0}\right\}$ with the quasi-norm $\left|a_{0}\right|_{0}=\operatorname{deg} a_{0}$, and $\mathfrak{A}_{1}=\{2 \pi$-periodic functions $a\}$ with the norm $|a|_{1}=\|a\|_{L^{2}(\mathbb{T})}$, as well as, $E\left(n, a ; \mathfrak{A}_{0}, \mathfrak{A}_{1}\right)=\inf \left\{\left\|a-a_{0}\right\|_{L^{2}(\mathbb{T})}: \operatorname{deg} a_{0}<n\right\}$ for all $a \in L^{2}(\mathbb{T})$. Let $c_{j, \tau}:=\left\{\begin{array}{cl}{\left[\frac{j}{\tau(j+1)^{2}}\right]^{1 / \tau}} & \text { if } \tau<\infty \\ 1 & \text { if } \tau=\infty\end{array}\right.$ with $j \in \mathbb{N}$. Then BernsteinJackson inequalities have the form

$$
\begin{aligned}
n^{j} E(n, a) & \leq c_{j, \tau}|a|_{\mathcal{B}_{\tau}^{j}} \leq 2^{1 / 2}|a|_{0}^{j}|a|_{1} \quad \text { for all } \quad a \in \mathfrak{A}_{0} \cap \mathfrak{A}_{1}, \\
E(n, a) & \leq n^{-j} c_{j, \tau}|a|_{\mathcal{B}_{\tau}^{j}} \text { for all } a \in \mathcal{B}_{\tau}^{j}\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right),
\end{aligned}
$$

where $\mathcal{B}_{\tau}^{s}\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)=\left(\mathfrak{A}_{0}, \mathfrak{A}_{1}\right)_{\vartheta, q}^{1 / \vartheta}$ with $j+1=1 / \vartheta \in \mathbb{N}, \tau=\vartheta q$.
Let $\mathfrak{A}=L^{2}(\mathbb{T})$. Consider the Banach space $L_{\mu}^{p}$ of $L^{2}(\mathbb{T})$-valued functions $f: X \rightarrow L^{2}(\mathbb{T})$. Then bilateral Bernstein-Jackson inequalities have the form

$$
n^{-j} 2^{-(j+1) / 2} f^{*}(n) \leq c_{j, \tau}\|f\|_{\tau / j} \leq\|f\|_{0}^{j}\|f\|_{\infty}, \quad f \in L_{\mu}^{0} \cap L_{\mu}^{\infty}
$$

$$
f^{*}(n) \leq n^{j} 2^{(j+1) / 2} c_{j, \tau}\|f\|_{\tau / j}, \quad f \in L_{\mu}^{\tau / j}
$$

where $f^{*}(n)=E\left(n, f ; L_{\mu}^{0}, L_{\mu}^{\infty}\right)=\inf \left\{\sigma: m\left(\sigma, f_{\sigma}\right) \leq t\right\}$ for all $f \in L_{\mu}^{\infty}$.

Example 3 (Applications to operator spectral approximations) Consider the example commonly used in foundations of quantum systems for describing quantum states (see e.g. [9, no 3.4]). Similar estimates of spectral approximations were early analyzed in the paper [7]. In what follows, we consider the spaces $L^{p}=L^{p}(\mathbb{R} ; \mathbb{R})$ of real-valued functions.

Let $H$ be a Hilbert complex space with the norm $\|\cdot\|_{H}=\langle\cdot \mid \cdot\rangle^{1 / 2}$ and a selfadjoint unbounded linear operator $T$ with the dense domain $\mathcal{D}(T) \subset H$ is given. By spectral theorem the measurable function $f$ from $T$ can be well defined using the following spectral expansions (see e.g. [9])

$$
T=\int_{\sigma(T)} \lambda \mu(d \lambda), \quad f(T)=\int_{\sigma(T)} f(\lambda) \mu(d \lambda)
$$

where $\mu$ is a unique projection-valued measure determined on its spectrum $\sigma(T) \subset \mathbb{R}$ with values in the Banach space of bounded linear operators $\mathcal{L}(H)$, which can be extended on $\mathbb{R} \backslash \sigma(A)$ as zero.

At beginning, we consider the case when for any Borel set $\Sigma \subset \mathbb{R}$ and any $\psi \in \mathcal{D}(A)$ the $\mathcal{L}(H)$-valued measurable function

$$
\Sigma \longmapsto f(\Sigma)=\int_{\Sigma} f(\lambda) \mu_{\psi}(d \lambda)
$$

belongs to $L^{\infty}$ with respect to the positive measure $\mu_{\psi}(d \lambda):=\langle\mu(d \lambda) \psi \mid \psi\rangle$, where $\|\psi\|_{H}=1$.

Consider the corresponding quadratic forms $f_{\psi}(\Sigma)=\langle f(\Sigma) \psi \mid \psi\rangle$ as measurable functions of $L^{2}$ and let $f_{\psi}^{*}$ be the suitable decreasing rearrangement. By Theorem 11 the inequalities (27) and (28) in this case take the form

$$
\begin{align*}
f_{\psi}^{*}(t) & \leq t^{1-1 / \theta} C_{\theta, q}\left\|f_{\psi}\right\|_{q \theta^{2} /(1-\theta)}, \quad f_{\psi} \in L_{\mu}^{q \theta^{2} /(1-\theta)}  \tag{29}\\
t^{-1+1 / \theta} f_{\psi}^{*}(t) & \leq C_{\theta, q}\left\|f_{\psi}\right\|_{q \vartheta^{2} /(1-\theta)} \leq 2^{1 / 2 \theta}\left\|f_{\psi}\right\|_{0}^{-1+1 / \theta}\left\|f_{\psi}\right\|_{\infty}, \quad f_{\psi} \in L_{\mu}^{0} \cap L_{\mu}^{\infty} \tag{30}
\end{align*}
$$

where $\left\|f_{\psi}\right\|_{\infty}=\sup _{\Sigma \subset \mathbb{R}}\left|f_{\psi}(\Sigma)\right|$ and $\left\|f_{\psi}\right\|_{0}=\mu_{\psi}\left(\operatorname{supp} f_{\psi}\right)$. Applying the estimation (26) from Corollary 8, we obtain

$$
\begin{equation*}
f_{\psi}^{*}(t) \leq \frac{2}{\pi t} \int|f(\lambda)| \mu(d \lambda) \quad \text { for all } \quad f_{\psi} \in L_{\mu}^{1} \tag{31}
\end{equation*}
$$

The inequality (29), (31) give error estimations (in quadratic forms terms) of spectral approximations $f_{\psi}(T)=\langle f(T) \psi \mid \psi\rangle$ by $f_{\psi}(\Sigma)$ with $\mu(\Sigma) \leq t$. The inequalities (30) characterise the approximation accuracy.

In another case, using the $\mathcal{L}(H)$-valued measurable uniformly bounded functions

$$
\tilde{f}: \Sigma \longmapsto \int_{\Sigma} f(\lambda) \mu(d \lambda), \quad f \in L_{\mu}^{1}
$$

belonging to $L_{\mu}^{1}(\mathbb{R}, \mathcal{L}(H))$, we same as above obtain the inequality

$$
\tilde{f}^{*}(t) \leq \frac{2}{\pi t}\left\|\int f(\lambda) \mu(d \lambda)\right\|_{\mathcal{L}(H)}
$$

Fig. 2 Graphs of the function $f(t)=10 \sqrt{\frac{2}{\pi t^{3}}} e^{-\frac{(t-2)^{2}}{2 t}}$ (dots) and its non-increasing rearrangement $f^{*}(t)$ (polygon), $(0<t<10)$

Fig. 3 Graphs of approximation $E(u, f)$ via $u^{-s} c_{s, \tau}\|f\|_{\mathcal{B}_{\tau}^{s}}(0<u<11, s=\tau=2)$ using Jackson's inequality

Example 4 (Samples of numerical calculations) The inequality (27) together with the exact value of the normalized constant $c_{s, \tau}$ are suitable for direct numerical calculations. Illustrate this on several graphs, taking as an example the inverse Gaussian distribution function.

Consider two-parameter inverse Gaussian distribution with support on $(0, \infty)$ that is given by

$$
f(t)=C \sqrt{\frac{l}{2 \pi t^{3}}} \exp \left(-\frac{l(t-m)^{2}}{2 m^{2} t}\right), \quad C, t>0
$$

with the mean $m>0$ and the shape parameter $l>0$. By Theorem 11

$$
\begin{aligned}
f^{*}(u)=E(u, f) & =\inf \left\{\left\|f-f_{\sigma}\right\|_{\infty}: m\left(\sigma, f_{\sigma}\right) \leq u\right\}, \\
m\left(\sigma, f_{\sigma}\right) & =\mu\left\{u \in(0, \infty):\left|f_{\sigma}(u)\right|>\sigma\right\}
\end{aligned}
$$

coincides with the non-increasing rearrangement of $f$ on $(0, \infty)$. As a result, we obtain

$$
f^{*}(u)=E(u, f) \leq c_{s, \tau} u^{-s}\|f\|_{\tau / s} \quad \text { for all } \quad f \in L_{\mu}^{\tau / s}
$$

where $L_{\mu}^{\tau / s}=\mathcal{B}_{\tau}^{s}\left(L_{\mu}^{0}, L_{\mu}^{\infty}\right)$ in accordance with Remark 2 and the equality (18).
The obtained results of numerical calculations are illustrated on Fig. 2,3,4.

Statements and Declarations: There are no conflicts and potential competing of interest to disclose.
